

Muna Gautam

1. Would you say that Deep Blue was intelligent? Explain.

I think Deep Blue was intelligent in some way as it was able to defeat the world's greatest chess player, Garry Kasparov. Deep Blue was able to consider millions of potential moves and select powerful moves in the game. This also indicates that it was able to demonstrate some kind of intelligence in the game. Deep Blue shows that computers can be extremely powerful in solving complex problems very quickly. In a situation where a chess match is being played, it may be able to calculate more quickly and accurately than the human being. However, in terms of feelings, creativity, and real life experiences, it can't be compared to human. Deep blue mainly operates on the basis of rules and data whereas humans operate on the basis of experience and judgement.

2. What contributed to Deep Blue's success and how? Who/what should get credit for it?

The success of Deep Blue was due to both the machine and the people that worked with it. The machine was powerful, and it was quick in making informed decisions on strong moves during the game. Also, the role of IBM engineers and chess experts was very important. They were responsible for the design of the system, coding of the programs and the incorporation of chess knowledge into the computer. If not for their efforts and planning, Deep Blue would not have been successful. So, there should be a sharing of the credit between man and machine. Humans supplied the knowledge, strategy, and design while the machine supplied speed and calculation power. It was a collaboration of man and machine.

Google Duplex demo

1. What implications do you think such digital assistants will have for people?

Digital assistants like Google Duplex can our make life easier by handling different task like booking appointments, making reservations, and getting information. They save time, improve convenience, and can assist elderly people or individuals with disabilities. Since they use Natural Language Understanding (NLU) and Deep Learning, they can understand human speech and respond naturally. However, they may also raise concerns about privacy and reduced human interaction.

2. What opportunities might it open for businesses?

Various kind of opportunities can be opened for businesses as Google Duplex can assist companies with boosting their customer service and efficiency. It can deal with repetitive calls, appointment, bookings and inquiries, which helps to ease the burden of employees. Computers can deliver quicker service and more efficiency to businesses. AI-powered

assistants can also operate around the clock, which can help businesses to save money, boost productivity, and enhance customer satisfaction.

3. Is Google Duplex narrow, general, or super AI? Explain.

Google Duplex is an example of Narrow AI because it has been made to help specific jobs like making phone calls, making bookings, and reservations. It uses Natural Language Understanding (NLU), Deep Learning, and speech recognition technologies to understand and respond to human conversations. It can deal with human interactions very well and sound human, but it cannot solve complex tasks other than its area of specialization. So, it's not called Super AI or General AI.

4. What impressed you most in this demo?

The most impressive part of the Google Duplex demo was to have a natural and human-like conversation where it was able to interpret various replies and keep the discussion going. Expressions like “mm-hmm” added to the interaction made it sound more realistic. Its ability to handle unexpected situations gracefully and without human assistance was the best part of this demo.

Turing Test

1. What the author has to say about the importance of the Turing test?

According to the author, the Turing Test is a very important test in the history of artificial intelligence because it turns a hard philosophical question into one that is more practical. Alan Turing proposed that the question be changed from "can machines think?" to "can a machine act like a human in conversation?" And the author suggested that we should test to see whether a machine can talk like human or not. Similarly, it helps in AI research to measure progress also.

2. How Turing test is conducted?

There were two participants, one is the human and the other is machine, and one of the human judges speaks to them. The judge wasn't able to see them, and he can only send messages via text. Once a discussion has been taken place, the judge has had to determine which is the human and which is the machine. And if the machine can confuse the judge and cause him to make a wrong selection, it has passed the test.

3. What Turing predicted would happen by 2000? Did it happen in your opinion?

By the year 2000, Turing believed that machines equipped with sufficient memory and computing power would be able to confuse approximately 30% of people in a brief conversation test. In my opinion I believe that this prediction has only partially occurred,

though. There is no AI bot that can consistently and convincingly pass the Turing Test. Similarly, today we have advanced AI chatbots that can sometimes confuse people in short conversation also.

4. What parts of Mitsuku's 2016 transcript resemble human conversation the most?

Simple and friendly responses like “How are you?” and “Better now that you're here” are some transcript parts that resemble human conversation most. Similarly, when chatbot gives short opinions like “I think so” and talks about football teams, it feels like more human casual conversation.

5. Who was Eugene Goostman?

Eugene Goostman was a chatbot that act as a Ukrainian boy of 13 years old. It was used in Turing Test to confuse judges by using humour and sometimes by avoiding direct answers.
